

[ROTATION APPARATUS]

Abstract

A rotation apparatus comprises a sleeve, a retaining means, a first base, a second base, a pivot and a pivot base. The sleeve passes through the first base and the second base and screws into the retaining means. The pivot is fixed onto the second base and the pivot base is coupled to the pivot. After mounting a display panel to a host body via the rotation apparatus, the display panel can be flipped open via the pivot/pivot base linkage and then rotated around the axis of the sleeve. Furthermore, the components constituting the rotation apparatus are easy to manufacture and assemble.
